**Composting At Home**

**Good For Your Garden—And The Environment!**

Composting yard waste and kitchen scraps is one of the best and easiest things you can do to reduce waste and grow a healthy, sustainable garden. Using compost in your garden recycles nutrients and organic matter that help grow trouble-free plants with less water, fertilizer or pesticides. Compost also builds healthy soil that absorbs and filters runoff, protecting streams from erosion and pollution.

Composting at home can also save you time and money. You won’t have to bag and drag yard waste to the curb for collection, pay to have it trucked to composting facilities or buy finished compost. Composting your food scraps keeps them out of costly landfills and reduces your garbage bills.

The following methods for composting your yard and kitchen scraps are described in this guide:

- Composting yard waste in piles, bins and turning systems.
- Pest-resistant composting of kitchen scraps using worm bins, food digesters and garden burial.

Additional methods of recycling organic wastes at home are described in two other guides:

- *Growing Healthy Soil* describes how to use garden trimmings as mulch to conserve moisture and build soil. It also explains how to use finished compost as mulch or to amend soil.
- *Natural Lawn Care* explains how to leave grass clippings on lawns to fertilize and improve your soil, and build healthy turf.

Read on to learn all about composting! Then call the WSU Master Gardener Hotline at (425) 357-6010 if you have questions or need other guides. Refer to the Resources section for bin building plans.

**Climate Change**

**Building Your Soil With Compost Can Help**

- Composting keeps yard and food waste out of landfills (where it would generate methane, a potent greenhouse gas).
- Compost builds the soil, removing carbon dioxide from the atmosphere and storing it as organic matter.
- Compost also reduces the need for chemical fertilizers and pesticides (another source of greenhouse gases), and composting at home reduces fuel burned for transport.

Be Climate Smart – Use Compost!

COMPOST: It’s GRRREAT For Your Garden!

Reducing waste is just the beginning of benefits from composting at home. When you use the finished compost in the garden the savings of time, effort and money just keep growing!

◆ Soil amendment. Mixing compost into the soil before planting improves every type of soil, and makes every plant grow better. Compost helps sandy soil hold water and nutrients. Compost also loosens clay soil so water is absorbed and drains better, roots can spread, weeds are easier to pull, and plants and soil life can breathe. Two to four inches of compost mixed into the top eight inches of soil throughout planting areas will make a difference for years to come.

◆ Mulch. An inch or two of compost spread on planting beds helps smother weeds, keeps moisture in the soil, and feeds valuable soil life and plants as it breaks down.

For more information on how to use compost in your yard and garden, see the Growing Healthy Soil guide.*

Choose The Best Composting System

There are lots of ways to make good compost—the best method is the one that is most convenient for you. Some common methods of composting yard waste are described below. Food scrap composting options are described in a later section.

Composting yard waste

Most garden waste (leaves, grass clippings, stalks and sticks, etc.) can be easily composted in simple bins without pest or odor problems—but only if food scraps are not added. Food scraps can create bad odors, and attract flies, rats and other pests. The following systems are ideal for composting yard waste. Refer to the Resources section for additional information on these methods.

◆ Piles are the simplest composting method, requiring no special tools or bins. However, open piles can easily become too wet if uncovered, can dry out, or can be disturbed by pets or other animals.

◆ Holding bins neatly contain composting materials, ward off animals and keep in moisture for efficient decomposition. Many types are available in stores, online, and in mail-order catalogs. They can also be made from wood pallets, wire fencing or hardware cloth, cement blocks, or other recycled materials.

◆ Turning systems are designed for quick, hot composting to handle large amounts of material. To make compost turning easy, use a series of bins, or a rotating barrel.

◆ Mulching and grasscycling are great ways to reuse yard trimmings in the garden. See the Growing Healthy Soil and Natural Lawn Care guides* for details on these practices.

Worm Bin Troubleshooting

Still having trouble? Call the WSU Master Gardener Hotline at (425) 357-6010—they’re the experts!—or e-mail them at mg.help@wsu.edu.
SECRETS FOR SUCCESSFUL YARD WASTE COMPOSTING

It’s not a secret—simply place garden waste in a pile and bacteria, bugs and fungi will turn it into compost—but it may take a year or longer. For quicker composting, provide the decomposer organisms with proper food and conditions:

1. A balanced diet.
   Composting bacteria thrive on a mix of succulent “greens,” like fresh grass clippings, annual weeds, and flowers, and on woody “browns,” such as autumn leaves and corn stalks. An equal mix of greens and browns works well. Too many greens can produce a smelly, soggy mess. A pile that is mostly browns takes a long time to decompose. The chart below lists common greens and browns.

2. Bite-sized pieces.
   Decomposers can break down small pieces quicker than large ones. For rapid composting, chop woody stalks or sticks so air can flow through. Let air into soggy piles by turning them and mixing in fresh grass clippings, annual weeds, and flowers, and on woodier fresh grass clippings, annual weeds, and flowers, and on woodier

   Materials should be moist but not dripping wet—like a wrung-out sponge. Spray and mix dry trimmings as they are added to the pile. Keep compost piles in the shade, and cover open piles with plastic.

4. Fresh air.
   If materials are too wet or compacted, composting will slow down and may create bad odors. Start with a good mix of materials including some coarse stalks or sticks so air can flow through. Let air into soggy piles by turning them and mixing in coarse stalks or dry straw.

WHAT CAN BE PUT IN HOME YARD WASTE COMPOST SYSTEMS?

<table>
<thead>

<tr>
<td>Coarse sawdust or shavings (small amounts)</td>
<td>Sawdust from plywood, treated or painted wood</td>
</tr>
<tr>
<td>Shredded paper, cardboard, paper towels, napkins or tissues</td>
<td>Coated photo or copy paper, colored paper, waxed cardboard</td>
</tr>
</tbody>
</table>

5. Pile size.
   A pile that is one cubic yard (3 x 3 x 3 feet) is ideal. Smaller piles dry out quickly, though bins with solid sides and a lid help keep small piles moist. Larger piles may need to be turned to let air into the middle.

6. Preventing pests and other problems.
   Use the chart below to avoid materials that may attract pests, create odors or cause other problems.

Worm Bin Composting

Worm bins are a fascinating way to turn food scraps into high-quality compost. Follow these easy steps to start your own worm bin. Check out Mary Appelhof’s book Worms Eat My Garbage for more detailed information on composting with worms.

Step 1. Get a bin.
   Use a sturdy wood or plastic box with a tight-fitting lid to keep pests out and moisture in. Holes drilled in the bottom are essential for drainage. Drill holes near the top of all sides for added ventilation; cover large holes with mesh to keep flies out. A box about 18 inches deep is best, since worms must live near the surface to breathe. Worm bins can be made from old cupboards or crates, or built with plywood. Bins made from recycled plastic are available online or through mail-order catalogs. Refer to the Resources section for additional information.

Step 2. Fill the bin with bedding.
   Carbon-rich bedding supplies worms with a balanced diet, and helps prevent flies and odors. Good beddings include moist autumn leaves, shredded cardboard or newspaper, or straw—a mix of these works best. Immerse dry bedding in a garbage can full of water for several minutes before adding to worm bin, or mix and spray with hose until everything is moist like a wrung-out sponge. Fill the bin to the top with loose bedding, to keep the worms from freezing in winter or getting too hot in summer. (Tip: save up a few bags of leaves each fall to rebed your bin later.)

Step 3. Add worms.
   Red worms, also known as “red wrigglers” or “manure worms,” are used for composting. “Earthworms” or “night crawlers” are not suitable for composting. Start with about a pound of worms (about one pint of pure worms) to keep up with food scraps. Get red worms from a friend’s bin or refer to the Resources section for additional information.

   Pull aside bedding to make holes or trenches large enough to lay food scraps 1 to 2 inches thick, and deep enough to cover scraps with a few inches of bedding. Bury in a different spot each week to give the worms a balanced diet of food scraps and bedding. Place a sheet of plastic or moist newspaper on top of the bedding to keep moisture in and flies out.

Step 5. Harvest compost and worms.
   After 6 to 12 months, most of the bedding should look dark, rich soil. To harvest compost and rebed the bin, push the compost to one side of the bin (it shrinks as it composts) and fill the empty side with fresh bedding. Then bury food scraps only in the new bedding until any food scraps in the old bedding finish decomposing, and most worms have migrated to the fresh food. Harvest finished compost and replace with fresh bedding.
   It is simple to pick out a few worms for fishing. To harvest more worms to start new bins, shovel a few gallons of compost into a pile in bright daylight. After 15 minutes, scrape away the outer layer of compost until many worms are visible. Repeat until worms are concentrated at the bottom of the pile.
Many books and articles recommend adding compost “activators” or “starters,” ground limestone, soil or finished compost to piles. None of these ingredients are essential for composting. Compost “activators” or “starters” usually contain nitrogen fertilizer, or dried enzymes or bacteria to “kick-start” decomposition. The nitrogen may be useful in a pile that has too many browns, but an organic nitrogen fertilizer is a less expensive way to get this nutrient. There are plenty of bacteria on yard trimmings ready to start decomposing when conditions are right.

**Food Digesters**

Food digesters are partially buried metal garbage cans or other containers with tight-fitting lids, and holes or mesh screens in the bottom providing access to the soil. Digesters provide more protection from pests than garden burial, and require less work than digging holes for burial or maintaining a worm bin. Follow these steps to start a digester:

**Step 1. Get a digester (or two).**

Digesters can be purchased through many garden supply catalogs, and building plans are available online for homemade food digesters. Refer to the Resources section for more information. Using two digesters makes management easy. One digester can be fed for active composting, while compost in the second finishes decomposing before harvest.

**Step 2. Select a spot.**

Find a convenient spot in the garden that has at least 18” of well-drained soil. If your soil drains poorly, consider building a mound of soil to set the digester in.

**Step 3. Dig a hole (or two), and install digesters.**

Use a shovel to dig a hole large enough to bury the base of the digester 17 inches deep, or according to the manufacturer’s instructions.

**Step 4. Add food scraps and cover material.**

Add layers of food scraps as they are generated. Covering each addition of food with a thin layer of shredded paper, sawdust, or coco-coir helps to speed composting and reduce flies, though it is not essential.

**Step 5. Harvest.**

Digesters can be fed for 6 to 12 months before they are full of food scraps. If you have two digesters, when the first is full, stop using it, and use your second digester for the next 6 to 12 months. When the second digester is full, shovel the finished compost out of the first unit for use in the garden, and begin using that unit again. If you only have one digester, shovel the compost and decomposing food scraps out of the digester when it gets full, and bury in the garden.
Quick and Hot Compost

**Ingredients:**
- 3 to 4 heaping wheelbarrows of fresh “greens.”
- 3 to 4 heaping wheelbarrows of “browns”
- Water (from a watering can or hose with spray head)

**Steps:**
1. Chop or shred coarse materials with a pruner, machete, shovel, lawn mower or shredded. 
2. Put roughly equal mix of “greens” and “browns” on a tarp or on the ground. 
3. Mix and spray materials with water until they glisten. 
4. Load mix into bin or stack in pile. Repeat until bin is full. 
5. Check heat in middle of pile by using a compost thermometer or by touch. When pile has heated and starts to cool (5 to 10 days), pull it apart and restack, putting materials from the outside edges into the middle and hot stuff from the middle of the pile on the top and sides. Ideally, the middle of the pile should heat up to 110 to 140°F—too hot to touch! 
6. Monitor pile and turn again when it cools. Cover and let cure for 6 weeks or more before using. It’s ready when most material is dark, crumbly and sweet-smelling like soil.

Cool and Easy Compost

**Ingredients:**
- “Green” and “brown” yard trimmings, as available. Do not use “Weed & Feed” treated grass clippings. 
- Water (from a watering can or hose with spray head)

**Steps:**
1. Put yard trimmings in bin as picked up from yard. Mix and moisten dry materials as they are added. Chop tough stalks using a machete or spade. 
2. Cover with plastic or bin lid after each addition. 
3. Dig into pile occasionally. If materials in the middle of the pile are not decomposing, check the Yard Waste Compost Troubleshooting chart. 
4. In 6 to 18 months pull aside fresh materials to harvest dark, crumbly, sweet-smelling finished compost at bottom of pile. Return undecomposed materials to bin.

**Steps To Successful Food Scrap Composting**

Food scraps can be a great source of nutrients for the garden. However, they are also attractive to disease-carrying pests like rats, and must be composted with care. Food scraps should only be composted in systems that keep out rodents and other pests. Meat, fish, poultry, dairy products and pet wastes should not be composted in any system at home—they break down slowly, create bad odors and attract pests. There are three simple and reliable ways to compost food scraps without pests:

- **Burying food scraps in the garden** is a simple method requiring no special tools.
- **Food “digesters”** provide a convenient and pest resistant way to compost food scraps.
- **Worm bins are a fun and interesting method for composting food scraps to produce rich compost and worms for fishing.**

**How Do I Store Food Scraps In The Kitchen?**

A plastic container with a lid is great for storing scraps in the kitchen until you are ready to take them outside. Empty the container into your worm bin, hole in garden or digester every two days so food scraps don’t start to smell. A 5-gallon bucket with tight lid can be used outside to store food scraps for longer periods if it is inconvenient to add them to the compost, but odors and flies may become a problem—especially in summer. Sprinkling an inch or two of sawdust, shredded newspaper, or coconut coir on top of layers helps prevent flies and odors. Food scraps can also be stored in a plastic container in the freezer to control these problems. Do what works best for you.

**Food Scrap Composting**

- **Greens:** fruit and vegetable trimmings, bread and grains, coffee grounds and filters, tea bags, fruit from yard.
- **Browns (bedding):** newspaper, cardboard, fall leaves, clean sawdust or shavings.

**Do not compost or bury**

- Meat, fish, poultry or dairy products—put in disposal or trash. 
- Pet wastes—bag in plastic and put in trash. 
- Evergreen leaves, sawdust or shavings from painted or treated wood, coated paper.
YARD WASTE COMPOST RECIPES

There are many ways to make good compost. Here are two basic recipes to help you get started. Choose the recipe that suits the amount of time and effort you want to spend.

Quick and Hot Compost
Made in batches that are ready to use in 2 to 3 months.

Ingredients:
– Enough to make a 3 x 3 x 3 foot pile, or fill a bin.
  – 3 to 4 heaping wheelbarrows of “browns”
  – 3 to 4 heaping wheelbarrows of “greens”.
  – Water (from a watering can or hose with spray head)

Steps:
1. Chop or shred coarse materials with a pruner, machete, shovel, lawn mower or shredder.
2. Put roughly equal mix of “greens” and “browns” on a tarp or on the ground.
3. Mix and spray materials with water until they glister.
4. Load mix into bin or stack in pile. Repeat until bin is full.
5. Check heat in middle of pile by using a compost thermometer or by touch. When pile has heated and starts to cool (5 to 10 days), pull it apart and restack, putting materials from the outside edges into the middle and hot stuff from the middle of the pile on the top and sides. Ideally, the middle of the pile should heat up to 110 to 140°F—too hot to touch! Monitor pile and turn again when it cools. Cover and let compost at bottom of pile return undecomposed materials to bin.
6. Monitor pile and turn again when it cools. Cover and let cure for 8 weeks or more before using. It’s ready when most material is dark, crumbly and sweet-smelling like soil.

Cool and Easy Compost
Built continuously as materials are available. Ready in 6 to 18 months.

Ingredients:
– “Green” and “brown” yard trimmings, as available. Do not use “Weed & Feed” treated grass clippings.
– Water (from a watering can or hose with spray head)

Steps:
1. Put yard trimmings in bin as picked up from yard. Mix and moisten dry materials as they are added. Chop tough stalks using a machete or spade.
2. Cover with plastic or bin lid after each addition.
3. Dig into pile occasionally. If materials in the middle of the pile are not decomposing, check the Yard Waste Compost Troubleshooting chart.
4. In 6 to 18 months pull aside fresh materials to harvest dark, crumbly, sweet-smelling finished compost at bottom of pile. Return undecomposed materials to bin.

FOOD SCRAPS IN THE KITCHEN?

A plastic container with a lid is great for storing scraps in the kitchen until you are ready to take them outside. Empty the container into your worm bin, hole in garden or digester every two days so food scraps don’t start to smell. A 5-gallon bucket with tight lid can be used outside to store food scraps for longer periods if it is inconvenient to add them to the compost, but odors and flies may become a problem—especially in summer. Sprinkling an inch or two of sawdust, shredded newspa, or coconut coir on top of layers helps prevent flies and odors. Food scraps can also be stored in a plastic container in the freezer to control these problems. Do what works best for you.

FOOD SCRAPS COMPOSTING

Food scraps can be a great source of nutrients for the garden. However, they are also attractive to disease-carrying pests like rats, and must be composted with care. Food scraps should only be composted in systems that keep out rodents and other pests. Meat, fish, poultry, dairy products and pet wastes should not be composted in any system at home—they break down slowly, create bad odors and attract pests. There are three simple and reliable ways to compost food scraps without pests:

- Burying food scraps in the garden is a simple method requiring no special tools.
- Food “digesters” provide a convenient and pest resistant way to compost food scraps.
- Worm bins are a fun and interesting method for composting food scraps to produce rich compost and worms for fishing.

STEPS TO SUCCESSFUL FOOD SCRAPS COMPOSTING

Food scraps can be a great source of nutrients for the garden. However, they are also attractive to disease-carrying pests like rats, and must be composted with care. Food scraps should only be composted in systems that keep out rodents and other pests. Meat, fish, poultry, dairy products and pet wastes should not be composted in any system at home—they break down slowly, create bad odors and attract pests. There are three simple and reliable ways to compost food scraps without pests:

- Burying food scraps in the garden is a simple method requiring no special tools.
- Food “digesters” provide a convenient and pest resistant way to compost food scraps.
- Worm bins are a fun and interesting method for composting food scraps to produce rich compost and worms for fishing.

WHAT CAN BE PUT IN HOME YARD WASTE COMPOST SYSTEMS?

Bury in garden, compost in worm bins or food digesters

- Greens: fruit and vegetable trimmings, bread and grains, coffee grounds and filters, tea bags, fruit from yard.
- Browns (bedding): newspaper, cardboard, fall leaves, clean sawdust or shavings.

Do not compost or bury

- Meat, fish, poultry or dairy products—put in disposal or trash.
- Pet wastes—bag in plastic and put in trash.
- Evergreen leaves, sawdust or shavings from painted or treated wood, coated paper.
Many books and articles recommend adding compost “activators” or “starters,” ground limestone, soil or finished compost to piles. None of these ingredients are essential for composting. Compost “activators” or “starters” usually contain nitrogen fertilizer, or dried enzymes or bacteria to “kick-start” decomposition. The nitrogen may be useful in a pile that has too many browns, but an organic nitrogen fertilizer is a less expensive way to get this nutrient. There are plenty of bacteria on yard trimmings ready to start decomposing when conditions are right.

Food Digesters
Food digesters are partially buried metal garbage cans or other containers with tight-fitting lids, and holes or mesh screens in the bottom providing access to the soil. Digesters provide more protection from pests than garden burial, and require less work than digging holes for burial or maintaining a worm bin. Follow these steps to start a digester:

Step 1. Get a digester (or two).
Digesters can be purchased through many garden supply catalogs, and building plans are available online for homemade food digesters. Refer to the Resources section for more information. Using two digesters makes management easy. One digester can be fed for active composting, while compost in the second finishes decomposing before harvest.

Step 2. Select a spot.
Find a convenient spot in the garden that has at least 18” of well drained soil. If your soil drains poorly, consider building a mound of soil to set the digester in.

Step 3. Dig a hole (or two), and install digesters.
Use a shovel to dig a hole large enough to bury the base of the digester 17 inches deep, or according to the manufacturer’s instructions.

Step 4. Add food scraps and cover material.
Add layers of food scraps as they are generated. Covering each addition of food with a thin layer of shredded paper, sawdust, or coco-coir helps to speed composting and reduce flies, though it is not essential.

Step 5. Harvest.
Digesters can be fed for 6 to 12 months before they are full of food scraps. If you have two digesters, when the first is full, stop using it, and use your second digester for the next 6 to 12 months. When the second digester is full, shovel the finished compost out of the first unit for use in the garden, and begin using that unit again. If you only have one digester, shovel the compost and decomposing food scraps out of the digester when it gets full, and bury in the garden.
SECRETS FOR SUCCESSFUL YARD WASTE COMPOSTING

It’s not a secret—simply place garden waste in a pile and bacteria, bugs and fungi will turn it into compost—but it may take a year or longer. For quicker composting, provide the decomposer organisms with proper food and conditions:

1. A balanced diet.
   Composting bacteria thrive on a mix of succulent “greens,” like fresh grass clippings, annual weeds, and flowers, and on woodier “browns,” such as autumn leaves and corn stalks. An equal mix of greens and browns works well. Too many greens can produce a smelly, soggy mess. A pile that is mostly browns takes a long time to decompose. The chart below lists common greens and browns.

2. Bite-sized pieces.
   Decomposers can break down small pieces quicker than large ones. For rapid composting, chop woody stalks with a shovel or machete, run over them with a lawn mower, or put them through a shredder.

   Materials should be moist but not dripping wet—like a wrung-out sponge. Spray and mix dry trimmings as they are added to the pile. Keep compost piles in the shade, and cover open piles with plastic.

4. Fresh air.
   If materials are too wet or compacted, composting will slow down and may create bad odors. Start with a good mix of materials including some coarse stalks or sticks so air can flow through. Let air into soggy piles by turning them and mixing in coarse stalks or dry straw.

5. Pile size.
   A pile that is one cubic yard (3 x 3 x 3 feet) is ideal. Smaller piles dry out quickly, though bins with solid sides and a lid help keep small piles moist. Larger piles may need to be turned to let air into the middle.

6. Preventing pests and other problems.
   Use the chart below to avoid materials that may attract pests, create odors or cause other problems.

WHAT CAN BE PUT IN HOME YARD WASTE COMPOST SYSTEMS?

<table>

| **Browns**                  |                        |
| Autumn leaves               | Large amounts of evergreen leaves, needles or cones |
| Twigs and stalks            | Branches over 1/2 inch diameter; berry brambles, rose stems, holly |
| Coarse sawdust or shavings (small amounts) | Sawdust from plywood, treated or painted wood |
| Shredded paper, cardboard, paper towels, napkins or tissues | Coated photo or copy paper, colored paper, waxed cardboard |

Worm Bin Composting

Worm bins are a fascinating way to turn food scraps into high-quality compost. Follow these easy steps to start your own worm bin. Check out Mary Appelhof’s book Worms Eat My Garbage for more detailed information on composting with worms.

Step 1. Get a bin.
   Use a sturdy wood or plastic box with a tight-fitting lid to keep pests out and moisture in. Holes drilled in the bottom are essential for drainage. Drill holes near the top of all sides for added ventilation; cover large holes with mesh to keep flies out. A box about 18 inches deep is best, since worms must live near the surface to breathe. Worm bins can be made from old cupboards or crates, or built with plywood. Bins made from recycled plastic are available online or through mail-order catalogs. Refer to the Resources section for additional information.

Step 2. Fill the bin with bedding.
   Carbon-rich bedding supplies worms with a balanced diet, and helps prevent flies and odors. Good beddings include moist autumn leaves, shredded card-board or newspaper, or straw—a mix of these works best. Immerse dry bedding in a garage can fill with water for several minutes before adding to worm bin, or mix and spray with hose until everything is moist like a wrung-out sponge.
   Fill the bin to the top with loose bedding, to keep the worms from freezing in winter or getting too hot in summer. (Tip: save up a few bags of leaves each fall to rebed your bin later.)

Step 3. Add worms.
   Redworms, also known as “red wrigglers” or “manure worms,” are used for composting. “Earthworms” or “night crawlers” are not suitable for composting. Start with about a pound of worms (about one pint of pure worms) to keep up with food scraps. Get red worms from a friend’s bin or refer to the Resources section for additional information.

   Pull aside bedding to make holes or trenches large enough to lay food scraps 1 to 2 inches thick, and deep enough to cover scraps with a few inches of bedding. Bury in a different spot each week to give the worms a balanced diet of food scraps and bedding. Place a sheet of plastic or moist newspaper on top of the bedding to keep moisture in and flies out.

Step 5. Harvest compost and worms.
   After 6 to 12 months, most of the bedding should look like dark, rich soil. To harvest compost and rebed the bin, push the compost to one side of the bin (it shrinks as it composts) and fill the empty side with fresh bedding. Then bury food scraps only in the new bedding until any food scraps in the old bedding finish decomposing, and most worms have migrated to the fresh food. Harvest finished compost and replace with fresh bedding.
   It is simple to pick out a few worms for fishing. To harvest more worms to start new bins, shovel a few gallons of compost into a pile in bright daylight. After 15 minutes, scrape away the outer layer of compost until many worms are visible. Repeat until worms are concentrated at the bottom of the pile.
**Stackable Worm Bins**
A number of worm bins are for sale that use stacking trays to take advantage of the worms’ tendency to feed on the surface and migrate out of finished compost. The top tray is fed fresh food scraps. When material in the bottom level is decomposed and worms move up into fresh materials, the tray is removed, harvested and then rebelled and replaced on top. For more information on these bins and where to get them, refer to the Resources section.

**COMPOST: It’s GRRREAT FOR YOUR GARDEN!**

Reducing waste is just the beginning of benefits from composting at home. When you use the finished compost in the garden the savings of time, effort and money just keep growing!

- **Soil amendment.** Mixing compost into the soil before planting improves every type of soil, and makes every plant grow better. Compost helps sandy soil hold water and nutrients. Compost also loosens clay soil so water is absorbed and drains better, roots can spread, weeds are easier to pull, and plants and soil life can breathe. Two to four inches of compost mixed into the top eight inches of soil throughout planting areas will make a difference for years to come.

- **Mulch.** An inch or two of compost spread on planting beds helps smother weeds, keeps moisture in the soil, and feeds valuable soil life and plants as it breaks down.

For more information on how to use compost in your yard and garden, see the *Growing Healthy Soil* guide.*

---

**CHOOSE THE BEST COMPOSTING SYSTEM**

There are lots of ways to make good compost—the best method is the one that is most convenient for you. Some common methods of composting yard waste are described below. Food scrap composting options are described in a later section.

**Composting yard waste**

Most garden waste (leaves, grass clippings, stalks and sticks, etc.) can be easily composted in simple bins without pest or odor problems—but only if food scraps are not added. Food scraps can create bad odors, and attract flies, rats and other pests. The following systems are ideal for composting yard waste. Refer to the Resources section for additional information on these methods.

- **Piles** are the simplest composting method, requiring no special tools or bins. However, open piles can easily become too wet if uncovered, can dry out, or can be disturbed by pets or other animals.

- **Holding bins** neatly contain composting materials, ward off animals and keep in moisture for efficient decomposition. Many types are available in stores, online, and in mail-order catalogs. They can also be made from wood pallets, wire fencing or hardware cloth, cement blocks, or other recycled materials.

- **Turning systems** are designed for quick, hot composting to handle large amounts of material. To make compost turning easy, use a series of bins, or a rotating barrel.

- **Mulching and grasscycling** are great ways to reuse yard trimmings in the garden. See the *Growing Healthy Soil* and *Natural Lawn Care* guides* for details on these practices.

Composting at Home

Good for your Garden—And the Environment!

Composting yard waste and kitchen scraps is one of the best and easiest things you can do to reduce waste and grow a healthy, sustainable garden. Using compost in your garden recycles nutrients and organic matter that help grow trouble-free plants with less water, fertilizer or pesticides. Compost also builds healthy soil that absorbs and filters runoff, protecting streams from erosion and pollution.

Composting at home can also save you time and money. You won’t have to bag and drag yard waste to the curb for collection, pay to have it trucked to composting facilities or buy finished compost. Composting your food scraps keeps them out of costly landfills and reduces your garbage bills.

The following methods for composting your yard and kitchen scraps are described in this guide:

- Composting yard waste in piles, bins and turning systems.
- Pest-resistant composting of kitchen scraps using worm bins, food digesters and garden burial.

Additional methods of recycling organic wastes at home are described in two other guides:

- Growing Healthy Soil describes how to use garden trimmings as mulch to conserve moisture and build soil. It also explains how to use finished compost as mulch or to amend soil.
- Natural Lawn Care explains how to leave grass clippings on lawns to fertilize and improve your soil, and build healthy turf.

Read on to learn all about composting! Then call the WSU Master Gardener Hotline at (425) 357-6010 if you have questions or need other guides. Refer to the Resources section for bin building plans.

Climate Change

Building Your Soil With Compost Can Help

- Composting keeps yard and food waste out of landfills (where it would generate methane, a potent greenhouse gas).
- Compost builds the soil, removing carbon dioxide from the atmosphere and storing it as organic matter.
- Compost also reduces the need for chemical fertilizers and pesticides (another source of greenhouse gases), and composting at home reduces fuel burned for transport.

Be Climate Smart – Use Compost!
